(54) Loop filtering method for reducing blocking effects and ringing noise of a motion-compensated image

(57) A signal adaptive loop filter reduces blocking effects and ringing noise of motion-compensated image data. In the loop filter, binary edge map information on which global thresholding and local thresholding with respect to the motion-compensated image are reflected, is used to judge whether the binary edge map information within a predetermined size of the filter window is either a homogeneous or an edge area. If it is judged as a homogeneous area, predetermined first weight factors corresponding thereto are used for gen-

erating a filtered pixel value corresponding to the corresponding filter window. While, in the case that it is judged as an edge area, predetermined second weight factors are varied according to the binary edge map information corresponding to pixels, and the filter window having the varied second weight factors is used for generating the filtered pixel value corresponding to respective corresponding pixels.

FIG. 2

EP 0 817 497 A2

Description

The present invention relates to a loop filtering method capable of reducing blocking effects and ringing noise, and more particularly, to a loop filtering method capable of reducing blocking effects and ringing noise of a motion-compensated image.

Most of picture coding standards including H.263 of International Telecommunication Union (ITU) and MPEG-1 and MPEG-2 of Organization for Standardization (ISO), use the block-based processing for motion estimation and discrete cosine transform (DCT).

This block-based processing induces the well-known blocking effects and ringing noise, in particular, when an image is highly compressed. The blocking effects induce a viewer who views a decompressed image displayed on a screen, to feel the boundary between the blocks in the visual sense. Typical blocking effects are grid noise in the monotone area and staircase noise along the image edges. The ringing noise induces sinusoidal traces on the practical edges of an image.

To solve the above problem, it is an object of the present invention to provide a loop filtering method capable of largely reducing blocking effects and ringing noise, by adaptively filtering a motion-compensated image data stored in a video memory of encoding and decoding systems.

To accomplish the above object of the present invention, there is provided a signal adaptive loop filtering method of largely reducing blocking effects and ringing noise, comprising the steps of:

- (a) generating binary edge map information by globally thresholding and locally thresholding the motion-compressed image;
- (b) judging whether the binary edge map information within a filter window corresponding to respective pixels is either homogeneous area or edge area, by using the binary edge map information belonging to a predetermined size of the filter window;
- (c) generating a filtered pixel value corresponding to a respective pixel using the filter window which has predetermined first weight factors related to the homogeneous area, when the binary edge map information corresponding to the respective pixel is judged as the homogeneous area in said step (b);
- (d) altering predetermined second weight factors according to the binary edge map information corresponding to the respective pixel when the binary edge map information is judged as the edge area in said step (b); and
- (e) generating a filtered pixel value corresponding to the respective pixel, using the filter window which has the altered second weight factors in said step (d).

By way of example, a specific embodiment of the invention will now be described, with reference to the accompanying drawings wherein :

Figure 1 is a block diagram showing an encoding apparatus employing a loop filter according to the preferred embodiment of the present invention;

Figure 2 is a block diagram illustrating a loop filter according to the preferred embodiment of the present invention;

Figure 3 is a conceptual view showing a binary edge map produced in a binary edge mapper of Figure 2;

Figure 4A shows a filter window for a 3x3 filter proposed in the present invention; Figure 4B shows weight factors for a 3x3 average filter; and Figure 4C shows weight factors for a 3x3 weighted filter.

Figure 1 is a block diagram showing an encoding apparatus employing a loop filter according to a preferred embodiment of the present invention, which shows an encoding apparatus related to H.263. In the Figure 1 apparatus, since blocks excepting a loop filter 310 proposed by the present invention are well-known to those who are concerned with high efficiency encoding systems including a prediction encoder, the operation with regard to such blocks will be described briefly.

Referring to Figure 1, an input video signal is input to a subtracter 301, a first switch 302 and a prediction encoder 309. The subtracter 301 subtracts a filtered signal by the loop filter 310 from the input video signal, an output signal of which is applied to the first switch 302. The first switch 302 selects either the input video signal or the output signal of the subtracter 301 according to the control of an encoding controller 305, and the selected signal is applied to an orthogonal transformer 303. The encoding controller 305 controls the first switch 302 so that the input video signal is applied to the orthogonal transformer 303 in the case of an intra coding mode, and the output signal of the subtracter 301 is applied to the orthogonal transformer 303 in the case of an inter coding mode. A signal passing through the orthogonal transformer 303 and a quantizer 304 is applied to a video multiplexer encoder (not shown) and a dequantizer 306. The dequantizer 306 dequantizes the applied signal, and the dequantized signal is supplied to an inverse-orthogonal transformer 307. An adder 308 adds an output signal of a second switch 311 and that of the inverse-orthogonal transformer 307, and the added signal is supplied to the prediction encoder 309. The prediction encoder 309 performs a motion estimation and compensation using the input video signal and a video signal stored in an internal memory, and the resultant signal by the motion estimation and compensation is stored in the internal memory. The predic-

tion encoder 309 also outputs motion vector V obtained by the motion estimation to the video multiplexer encoder. The loop filter 310 in accordance to the present invention described below performs the filtering with regard to the picture stored in the prediction encoder 309. An output signal of the loop filter 310 is supplied to the subtracter 301 and the second switch 311. The second switch 311 which is controlled by the encoding controller 305, cuts off what the input signal has supplied to the adder 308 in the case of the intra coding mode, and makes the input signal supplied to the adder 308 in the case of the inter coding mode. The encoding controller 305 controls the above operation of Figure 1 apparatus, generates a flag P representing intra/inter modes, a quantizer indicator signal qz and a flag t representing whether or not a signal is transmitted.

Figure 2 is a block diagram showing the loop filter 310 of Figure 1 apparatus. The loop filter 310 of Figure 2 includes an image store 10, a binary edge mapping unit 100 and a signal adaptive filter portion 200. The image store 10 stores data supplied from the prediction encoder 309 in which the motion estimation and compensation encoding are performed. The binary edge mapping unit 100 includes a gradient image generator 20, a global edge mapper 30, a local edge mapper 40 and a logical OR unit 50, which generates binary edge map information on which global edges and local edges of a motion-compensated image are reflected. The signal adaptive filter portion 200 includes a filter determiner 60, an average filter 70 and a weighted filter 80, which filters the motion-compensated image data using one of the average filter and the weighted filter to be described below based on the binary edge map information. The grid noise and the ringing noise are mitigated in the signal adaptive filter portion 200.

The gradient image generator 20 generates gradient image data using the image data stored in the image store 10. The gradient image generator 20 applies a vertical Sobel gradient operator and a horizontal Sobel gradient operator to the motion-compensated image, that is, the image data stored in the image store 10, so as to generate a gradient image. The gradient image data obtained by the gradient image generator 20 is supplied to the global edge mapper 30 and the local edge mapper 40.

The global edge mapper 30 produces a global edge map with respect to the whole image, and the local edge mapper 40 divides the whole image into blocks having a predetermined magnitude and produces a local edge map with respect to each of blocks. In more detail, the global edge mapper 20 calculates an edge value (i, j) corresponding to each pixel using the following equation (1).

$$\text{If } |\nabla_h| + |\nabla_v| \geq T_g \text{ edge } (i, j) = 1 \quad (1)$$

$$\text{Otherwise edge } (i, j) = 0$$

5 Here ∇_h and ∇_v represent a horizontal gradient image and a vertical gradient image at a location (i, j) obtained by the horizontal Sobel gradient operator and the vertical Sobel gradient operator, respectively. $|\nabla_h| + |\nabla_v|$ represents a gradient value at a location (i, j) and T_g is a global threshold value which is "100" when each pixel within an image has 256 gray levels.

10 Therefore, if a gradient value corresponding to a pixel of the location (i, j) is larger than or equal to the global threshold value T_g , the global edge mapper 30 determines an edge value corresponding to the pixel as "1". On the other hand, if a gradient value corresponding to a pixel is smaller than the global threshold value T_g , the global edge mapper 30 determines an edge value (i, j) corresponding to the pixel as "0". The global edge map information obtained by applying the above equation to the whole image is supplied to the logical OR unit 50.

15 The local edge mapper 40 produces a local edge map using the output of the gradient image generator 20. The local edge mapper 40 calculates a local threshold value with respect to each of all $M_1 \times M_2$ blocks of the gradient image, and calculates local edge values with respect to all gradient values contained in corresponding block using the calculated local threshold value. The block-based processing techniques, such as DCT transform and quantization, process signals with respect to an 8x8 block containing basically 8x8 pixels. Thus, the local edge mapper 40 according to the one embodiment of the present invention is also designed to draw a local edge map by using an 8x8 block. However, it will be apparent to a person skilled in the art that the present invention is not limited to the block of such a size.

20 35 The local threshold value T_n with respect to a n-th 8x8 block in the gradient image is defined by the following equations (2) - (4).

$$40 T_n = |1 - \frac{\sigma_n}{m_n}| \times T_g \quad (2)$$

wherein,

$$45 \sigma_n = \sqrt{\frac{1}{N} \sum_{(i,j) \in R_n} \{g(i,j) - m_n\}^2} \quad (3)$$

$$50 m_n = \frac{1}{N} \sum_{(i,j) \in R_n} g(i,j) \quad (4)$$

55 Here, $g(i,j)$ represents a gradient value, R_n represents a n-th 8x8 block region m_n and σ_n represent a mean value and a standard deviation of a n-th 8x8 block of the gradient image, respectively. T_g represents a global threshold value and N is 64 in the case of an 8x8 block. If the n-th 8x8 block is homogenous, a ratio σ_n/m_n

tends to be "0" with the result that T_n becomes very close to T_g . Meanwhile, if the n-th 8x8 block is part of a complicated image, the ratio σ_n/m_n increases. As a result, T_n becomes smaller than T_g . This small T_n is used in drawing a detail edge map which is not classified as a global edge by T_g .

The local edge mapper 40 individually compares the local threshold value T_n with respect to the n-th 8x8 block with a part of the gradient values within the block, in magnitude. Here, the part of the gradient values corresponds to 6x6 pixels within the 8x8 block excluding the boundary pixels within the 8x8 block. If the gradient value used for drawing the local edge map is defined as described above, the detailed information is protected from blurring, and the grid noise is prevented from being detected as an image edge. If each gradient value being allowable within the n-th 8x8 block region R_n is larger than or equal to the local threshold value T_n , the local edge mapper 40 determines a local edge value corresponding to the gradient value as "1". Meanwhile, if a gradient value corresponding to a pixel is smaller than the local threshold value T_n , the local edge mapper 40 determines a local edge value corresponding to the gradient value as "0". The local edge mapper 40 generates local edge map information by performing the operation procedure including an 8x8 block division, local edge value calculation and calculation of a local edge value with respect to all gradient values generated by the gradient image generator 20. The generated local edge map information is supplied to the logical OR unit 50.

The logical OR unit 50 performs a logical OR operation of the global edge map information and the local edge map information which are related to each other with respect to a pixel location. The logical OR unit 50 performs a logical OR operation with respect to all global edge values on the global edge map and all local edge values on the local edge map, and outputs binary edge map information representing the result to the filter determiner 60. The binary edge map produced by the logical OR unit 50 is conceptually shown in Figure 3. On the binary edge map of Figure 3, the shaded squares are represented the edge points each of which has the edge value "1".

The filter determiner 60 stores the binary edge map information supplied from the logical OR unit 50. The motion compensated image is classified into two areas such as an edge area and a homogeneous area by a binary edge map. For this classification, the present invention uses the filter determiner 60. The average filter 70 and the weighted filter 80 described later use a 3x3 filter window. Thus, a filter window used in the filter determiner 60 has a 3x3 size, too.

The filter determiner 60 judges whether a region on the binary edge map where the filter window is located is an edge area or a homogeneous area, based on the edge values contained in the filter window having a pre-determined size, that is the 3x3 size. If it is judged as a

homogeneous area, the filter determiner 60 outputs position data with respect to the central point in the filter window used for judgement, to the average filter 70. In the case that it is judged as an edge area, the filter determiner 60 outputs the binary edge map information and position data with respect to the central point in the filter window used for judgement, to the weighted filter 80. Here, the central point represents a point where the pixel value located at the point is replaced with a new value by filtering.

Figures 4A-4C relate to a two-dimensional 3x3 filter. Figure 4A shows a filter window for a 3x3 filter. Figure 4B shows the weight factors for the 3x3 average filter, and Figure 4C shows the weight factors for the 3x3 weighted filter. It is allowable that the weight factor of the central point shown in Figure 4C is replaced by 2. In the filter window of Figure 4A, the central point of the filter window is a point where an index value of the filter weight factor is "2".

The average filter 70 and the weighted filter 80 are a sort of two-dimensional low-pass filters, the operation of which will be described as follows.

If position data with respect to the central point is input, the average filter 70 reads the pixel values necessary to calculate the filtered pixel value of the central point from the image store 10. Then, the average filter 70 calculates the filtered pixel values using the read pixel values and the weight factors shown in Figure 4B. The calculated filtered pixel value is used as an altered pixel value with respect to the central point. The weighted filter 80 performs a filtering operation based on the binary edge map information and the position data supplied from the filter determiner 60 with respect to the central point. The operation of the weighted filter 80 will be described below in more detail.

If the central point "5" of the filter window is an edge point, the weighted filter 80 does not perform a filtering operation for the central point. If the edge point or the edge points are positioned in the 3x3 filter window excluding the central point, the weighted filter 80 performs a filtering operation using the weight factors shown in Figure 4C.

If any edges are on the points 2 and 6, 6 and 8, 4 and 8 or 2 and 4 in Figure 4A, the weight factors of the edge pixel and the outer neighbour pixels are set to zero. The signal adaptive filtered image data obtained by the average filter 70 and the weighted filter 80 are supplied to the image store 10.

The image store 10 replaces a corresponding pixel value by using the image data supplied from the average filter 70 and the weighted filter 80. Accordingly, the image store 10 stores the signal adaptive filtered image data with respect to all pixels in the image applied from the prediction encoder 309. The image store 10 outputs image data to be used in the subtractor 301 and the adder 308 of Figure 1.

Although the above one embodiment illustrates the loop filtering with regard to an image output from a pre-

diction encoder, it will be obvious to a person skilled in the art that a modification of performing loop filtering with respect to the image stored in a frame memory of the prediction encoder is made.

Although the above embodiment is illustrated with reference to an encoder, it will be apparent to a person skilled in the art that the loop filter can be also used in motion-compensated image data of a decoding apparatus. Furthermore, description relating to H.263 in this embodiment is made, but verification model VM 2. 1 of MPEG-4 can be equally used.

As described, the loop filtering method according to the present invention reduces the blocking effects and the ringing noise from the motion-compensated image, thereby providing an effect of improving the quality of the decompressed image.

While only certain embodiments of the invention have been specifically described herein, it will be apparent that numerous modifications may be made thereto without departing from the spirit and scope of the invention.

The reader's attention is directed to all papers and documents which are filed concurrently with or previous to this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, may be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive.

Each feature disclosed in this specification (including any accompanying claims, abstract and drawings), may be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features.

The invention is not restricted to the details of the foregoing embodiment(s). The invention extends to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any novel one, or any novel combination, of the steps of any method or process so disclosed.

Claims

1. A signal adaptive loop filtering method for a motion-compensated image, said signal adaptive loop filtering method comprising the steps of:

- (a) generating binary edge map information by globally thresholding and locally thresholding the motion-compressed image;
- (b) judging whether the binary edge map infor-

mation within a filter window corresponding to respective pixels is either homogeneous area or edge area, by using the binary edge map information belonging to a predetermined size of the filter window;

- (c) generating a filtered pixel value corresponding to a respective pixel using the filter window which has predetermined first weight factors related to the homogeneous area, when the binary edge map information corresponding to the respective pixel is judged as the homogeneous area in said step (b);
- (d) altering predetermined second weight factors according to the binary edge map information corresponding to the respective pixel when the binary edge map information is judged as the edge area in said step (b); and
- (e) generating a filtered pixel value corresponding to the respective pixel, using the filter window which has the altered second weight factors in said step (d).

2. The signal adaptive filtering method according to claim 1, wherein said step (a) comprises the steps of :

- (a1) generating a gradient image corresponding to the motion-compressed image;
- (a2) generating global edge map information which is composed of edge values corresponding to the respective pixels of the motion-compressed image, by comparing the predetermined first thresholding value with a gradient value corresponding to the respective pixels within the gradient image;
- (a3) generating local edge map information which is composed of edge values corresponding to the respective pixels of the motion-compressed image, by comparing gradient values within a predetermined size of individual blocks into which the motion-compressed image is divided, with a predetermined second thresholding value corresponding to the block; and
- (a4) logically summing an edge value in the global edge map information, and a corresponding edge value in the local edge map information, and generating binary edge map information.

3. The signal adaptive filtering method according to claim 2, wherein said step (a3) calculates the second thresholding value corresponding to respective blocks using the following equation :

$$T_n = |1 - \frac{\sigma_n}{m_n}| \times T_g$$

wherein,

$$\sigma_n = \sqrt{\frac{1}{N} \sum_{(i,j) \in R_n} \{g(i,j) - m_n\}^2}$$

$$m_n = \frac{1}{N} \sum_{(i,j) \in R_n} g(i,j)$$

Here, $g(i,j)$ represents a gradient value, R_n represents a n -th $8x8$ block region, m_n and σ_n represent a mean value and a standard deviation of a n -th $8x8$ block of the gradient image and T_g represents a global threshold value.

4. The signal adaptive filtering method according to claim 3, wherein said step (a3) compares the gradient values corresponding to $6x6$ pixels within a $8x8$ block excluding boundary pixels within the $8x8$ block with the corresponding second thresholding value. 15
5. The signal adaptive filtering method according to claim 1, wherein the more the predetermined second weight factors move from the centre of the filter window to the boundary thereof, the less the predetermined second weight factors have. 20
6. The signal adaptive filtering method according to claim 5, wherein said filter window has a $3x3$ size. 25
7. The signal adaptive filtering method according to claim 6, wherein said step (c) uses a filter window having the same magnitude of first weight factors. 30
8. The signal adaptive filtering method according to claim 7, wherein the magnitude of said first weight factors is "1". 35
9. The signal adaptive filtering method according to claim 8, wherein a second weight factor corresponding to said central point is "2" in magnitude, and second weight factors corresponding to the others thereof are "1". 40
10. The signal adaptive filtering method according to claim 8, wherein a second weight factor corresponding to said central point is "3" in magnitude, and second weight factors corresponding to the others thereof are "1". 45
11. The signal adaptive filtering method according to claim 8, wherein said step (d) comprises the step of resetting, as zero, second weight factors corresponding to positions put on a diagonal line and second weight factors corresponding to the outer neighbour of positions placed on the diagonal line, if the binary edge map information which corre- 50
55

sponds to positions on the diagonal lines among the positions excluding the central point of the $3x3$ sized filter window is represented as all edge points.
